# Linked Lists: Locking, Lock-Free, and Beyond ...

Companion slides for
The Art of Multiprocessor
Programming
by Maurice Herlihy & Nir Shavit

# Coarse-Grained Synchronization

- Each method locks the object
  - Avoid contention using queue locks
  - Easy to reason about
    - In simple cases
  - Standard Java model
    - Synchronized blocks and methods
- So, are we done?

# Coarse-Grained Synchronization

- Sequential bottleneck
  - Threads "stand in line"
- Adding more threads
  - Does not improve throughput
  - Struggle to keep it from getting worse
- · So why even use a multiprocessor?
  - Well, some apps inherently parallel ...

# First: Fine-Grained Synchronization

- Instead of using a single lock ..
- Split object into
  - Independently-synchronized components
- Methods conflict when they access
  - The same component ...
  - At the same time

#### Set Interface

- Unordered collection of items
- No duplicates
- Methods
  - add(x) put x in set
  - remove(x) take x out of set
  - contains(x) tests if x in set

```
public interface Set<T> {
  public boolean add(T x);
  public boolean remove(T x);
  public boolean contains(T x);
}
```

```
public interface Set<T> {
  public boolean add(T x);
  public boolean remove(T x);
  public boolean contains(T x);
}
```

Add item to set

```
public interface Set<T> {
   public boolean add(T x);
   public boolean remove(T x);
   public boolean contains(IT x);
}
```

Remove item from set

```
public interface Set<T> {
 public boolean add(T x);
 public boolean remove(T x):
public boolean contains(T x);
                     Is item in set?
```

```
public class Node {
  public T item;
  public int key;
  public Node next;
}
```

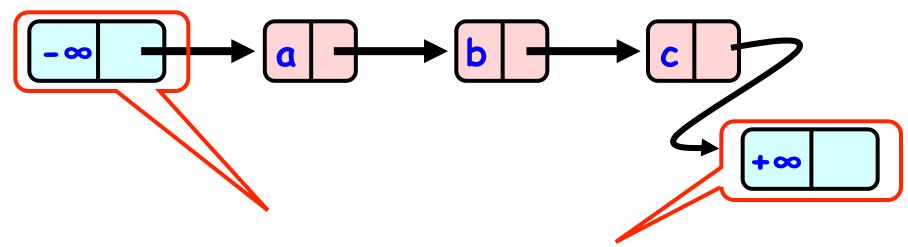

```
public class Node {
  public T item;
  public int key;
  public Node next;
}

item of interest
```

```
public class Node {
 nublic T item:
public int key;
                Usually hash code
```

```
public class Node {
  public T item;
  public int key;
  public Node next;
}
Reference to next node
```

#### The List-Based Set

Sorted with Sentinel nodes (min & max possible keys)

# Reasoning about Concurrent Objects

- Invariant
  - Property that always holds
- Established because
  - True when object is created
  - Truth preserved by each method
    - Each step of each method

# Specifically ...

- Invariants preserved by
  - add()
  - remove()
  - contains()
- Most steps are trivial
  - Usually one step tricky
  - Often linearization point

#### Interference

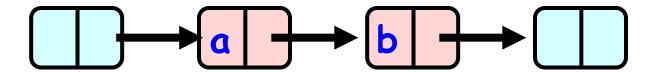

- · Invariants make sense only if
  - methods considered
  - are the only modifiers
- · Language encapsulation helps
  - List nodes not visible outside class

#### Interference

- Freedom from interference needed even for removed nodes
  - Some algorithms traverse removed nodes
  - Careful with malloc() & free()!
- Garbage-collection helps here

# Abstract Data Types

· Concrete representation

- Abstract Type
  - $\{a, b\}$

# Abstract Data Types

 Meaning of rep given by abstraction map

# Rep Invariant

- Which concrete values meaningful?
  - Sorted?
  - Duplicates?
- Rep invariant
  - Characterizes legal concrete reps
  - Preserved by methods
  - Relied on by methods

#### Blame Game

- · Rep invariant is a contract
- Suppose
  - add() leaves behind 2 copies of x
  - remove() removes only 1
- Which one is incorrect?

#### Blame Game

- Suppose
  - add() leaves behind 2 copies of x
  - remove() removes only 1
- Which one is incorrect?
  - If rep invariant says no duplicates
    - add() is incorrect
  - Otherwise
    - remove() is incorrect

# Rep Invariant (partly)

- Sentinel nodes
  - tail reachable from head
- Sorted
- No duplicates

# Abstraction Map

```
S(head) =
-{x | there exists a such that
a reachable from head and
a.item = x
```

# Sequential List Based Set

#### Add()

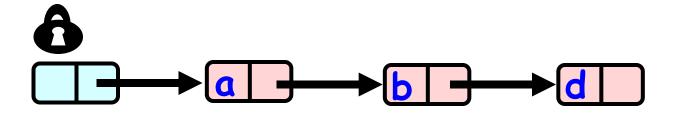

#### Remove()

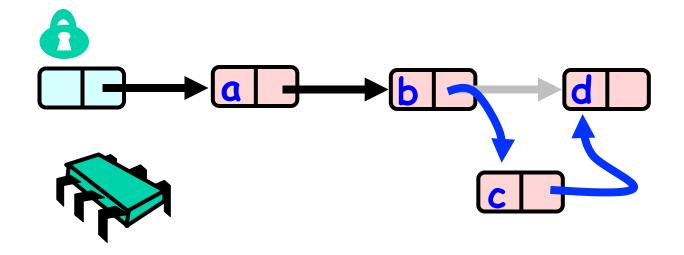

# Sequential List Based Set

# Add() Remove()

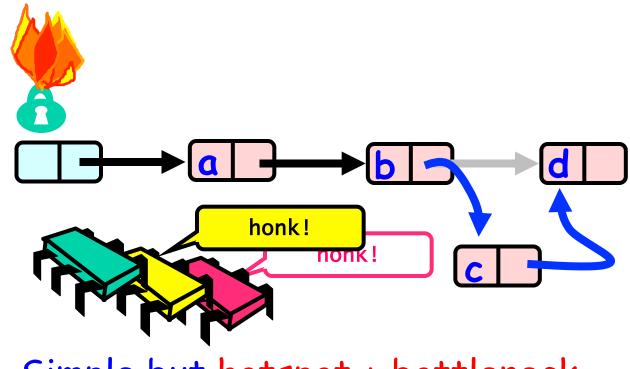

# Course Grained Locking

# Course Grained Locking

# Course Grained Locking

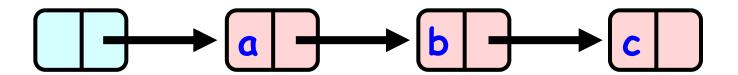

Simple but hotspot + bottleneck

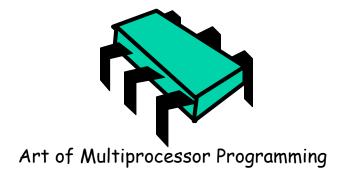

# Coarse-Grained Locking

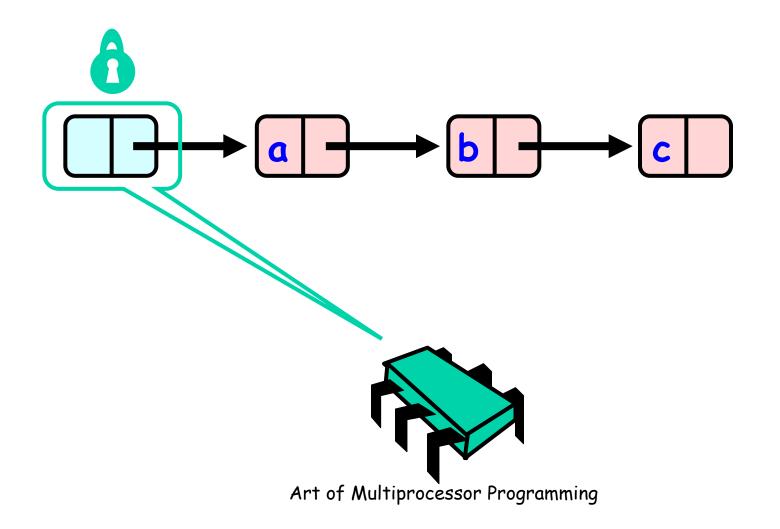

- · Easy, same as synchronized methods
  - "One lock to rule them all ..."
- · Simple, clearly correct
  - Deserves respect!
- Works poorly with contention
  - Queue locks help
  - But bottleneck still an issue

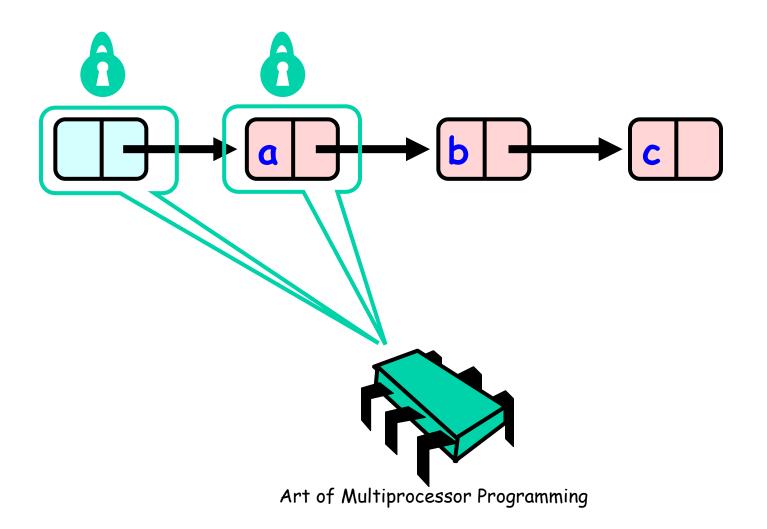

# Fine-grained Locking

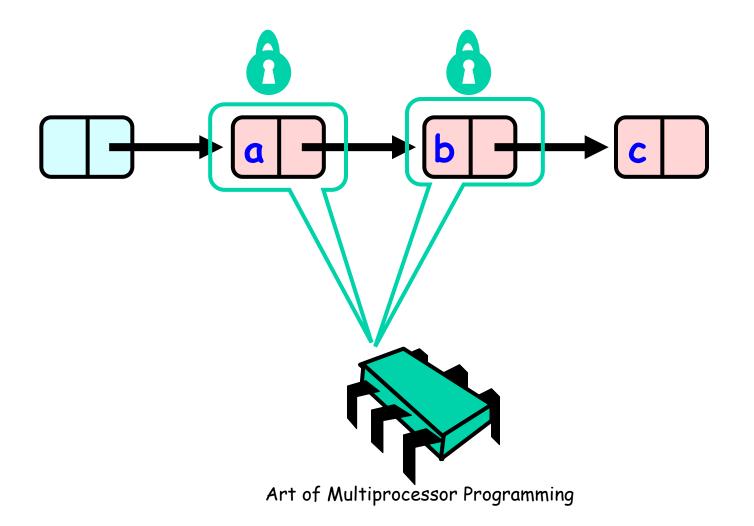

- · Requires careful thought
  - "Do not meddle in the affairs of wizards, for they are subtle and quick to anger"
- Split object into pieces
  - Each piece has own lock
  - Methods that work on disjoint pieces need not exclude each other

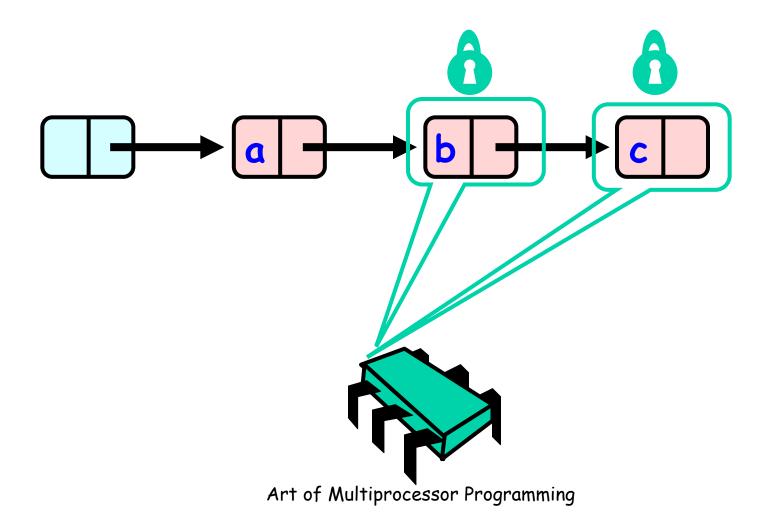

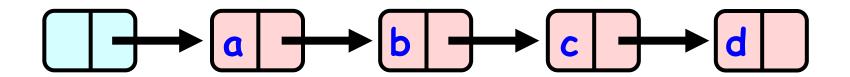

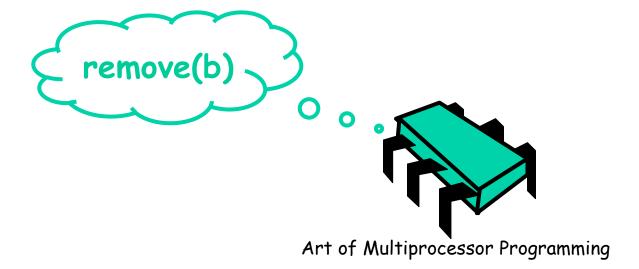

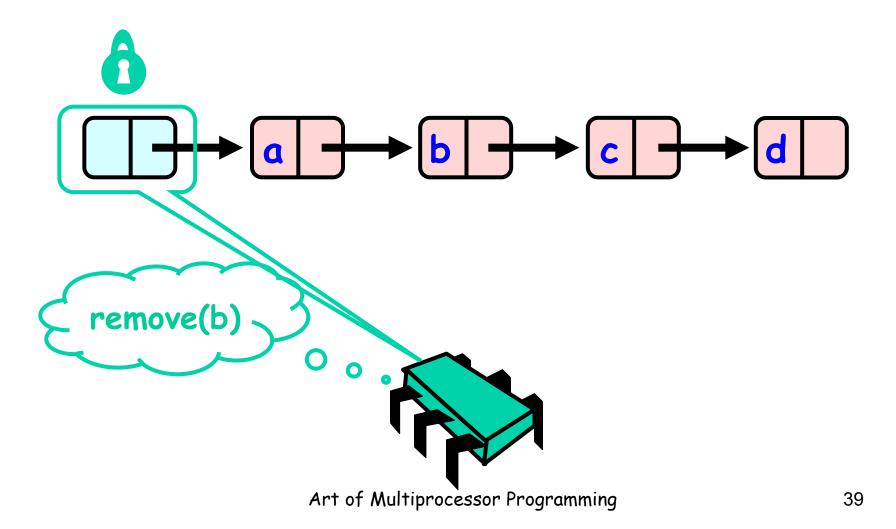

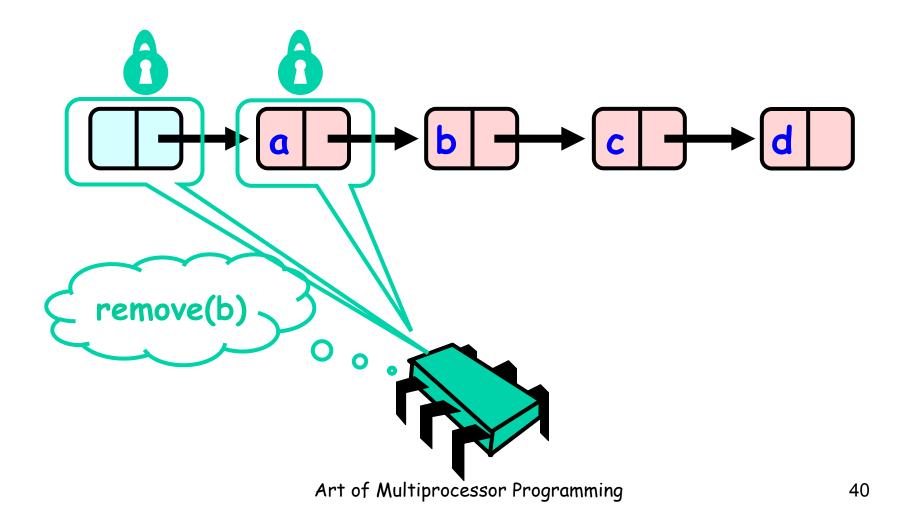

# Hand-over-Hand locking

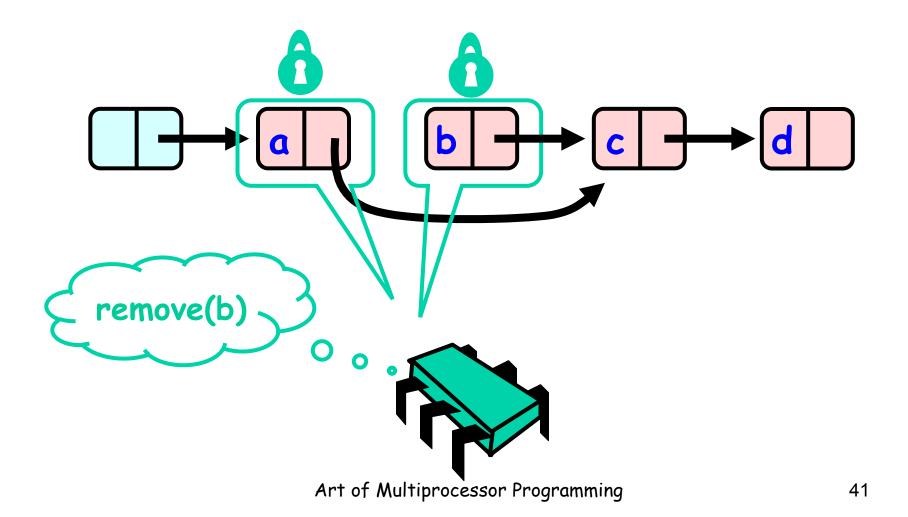

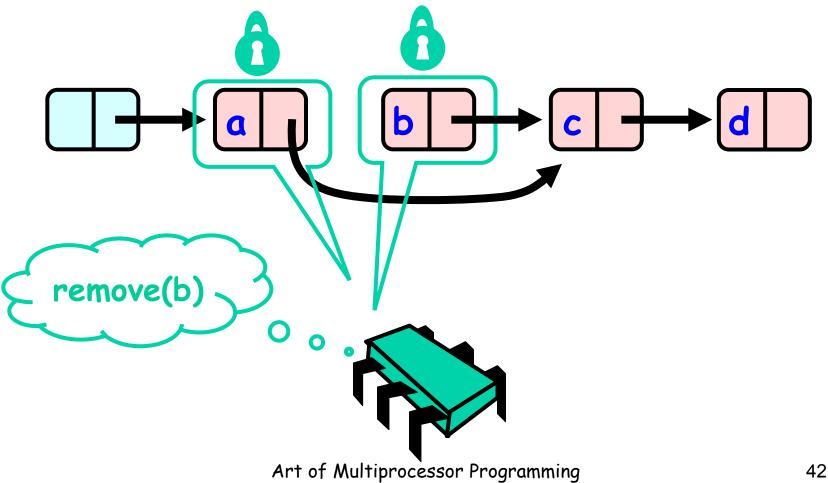

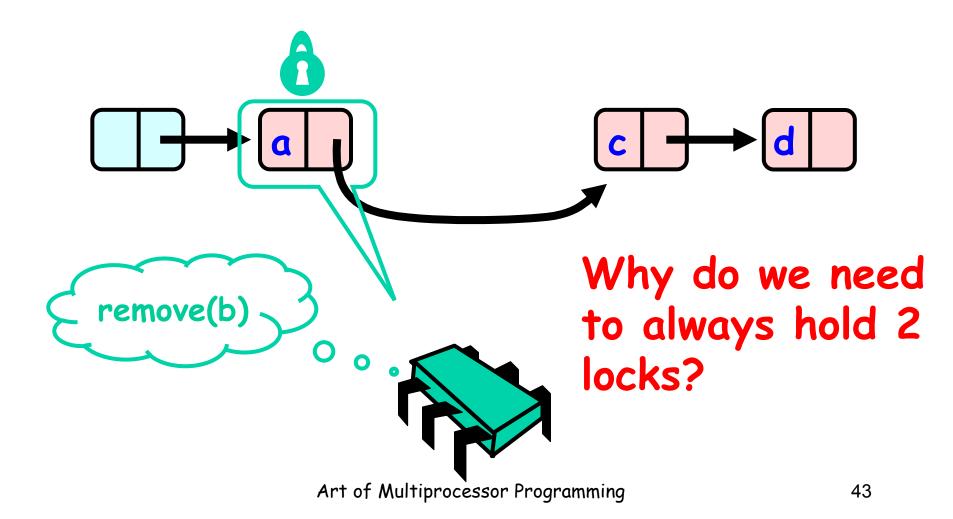

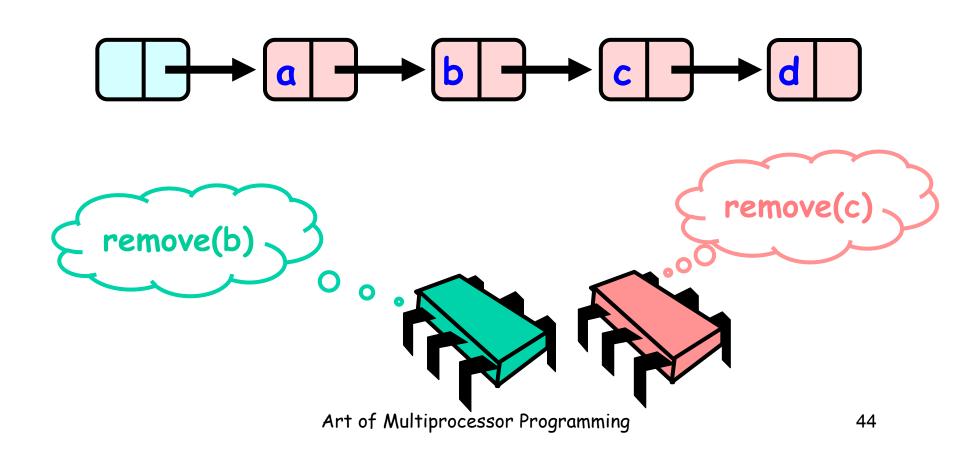

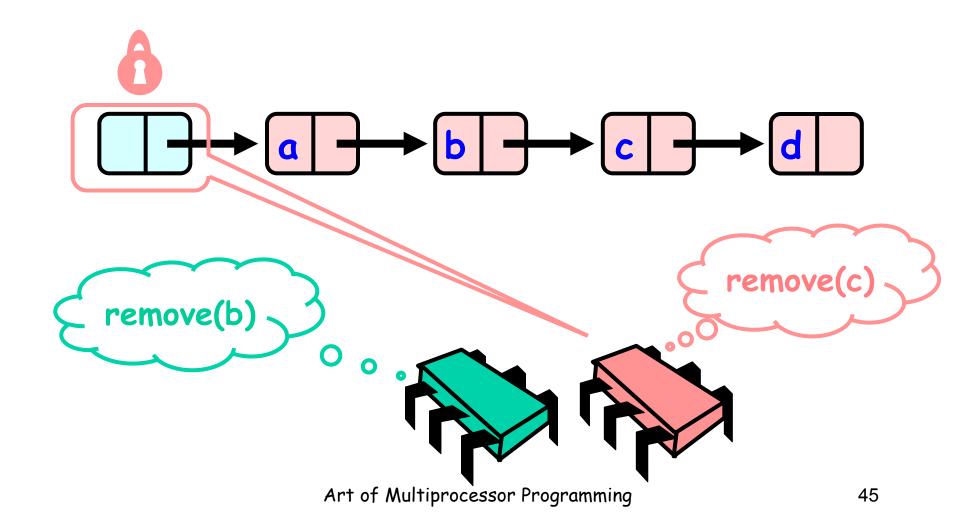

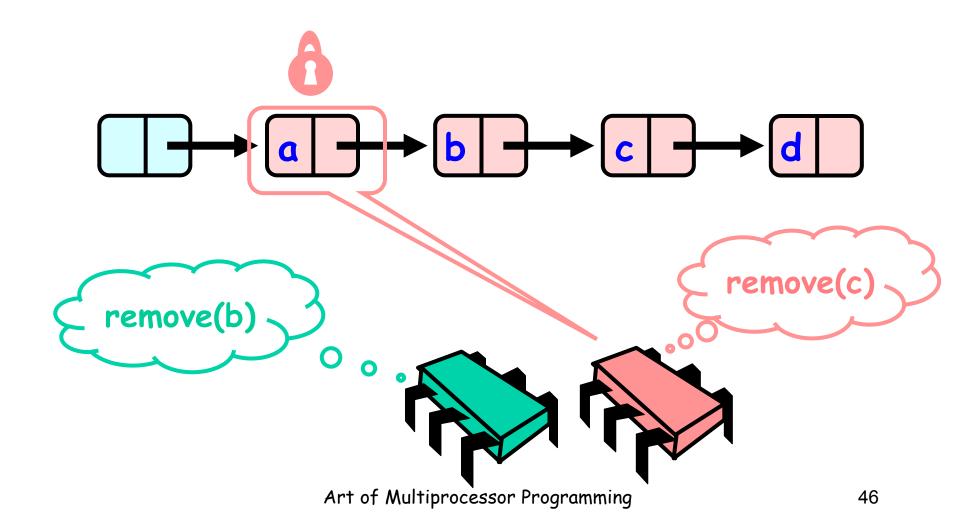

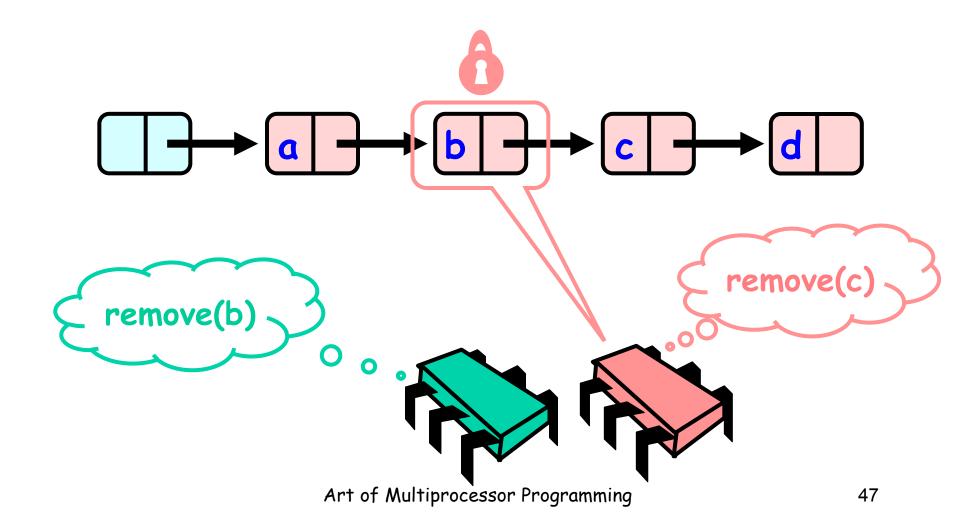

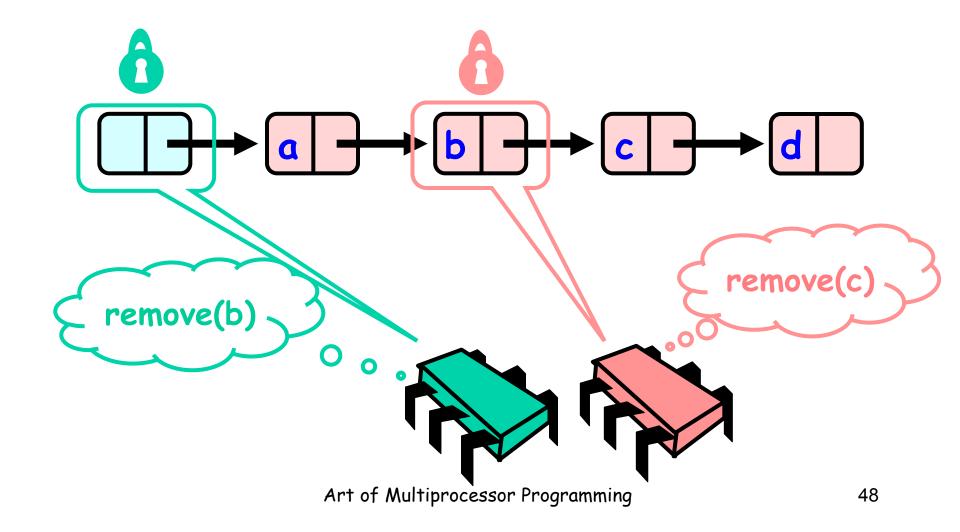

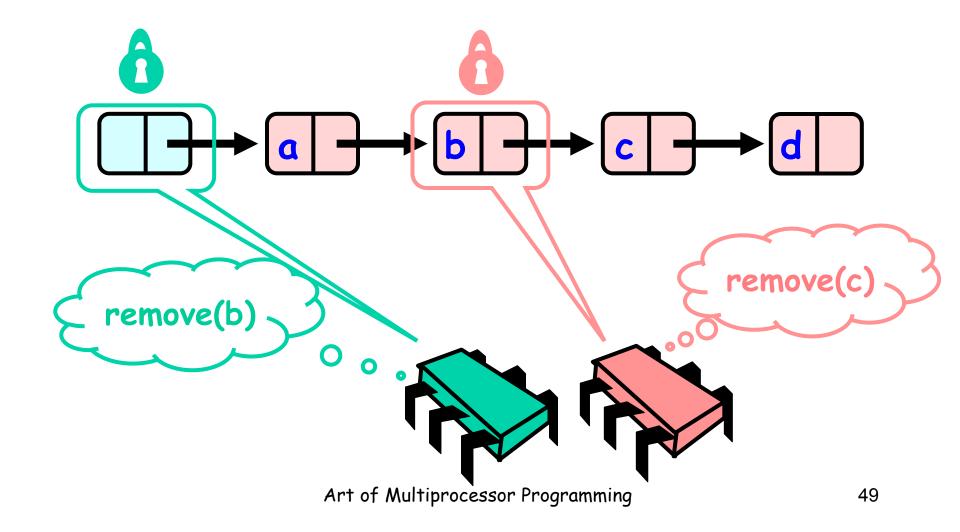

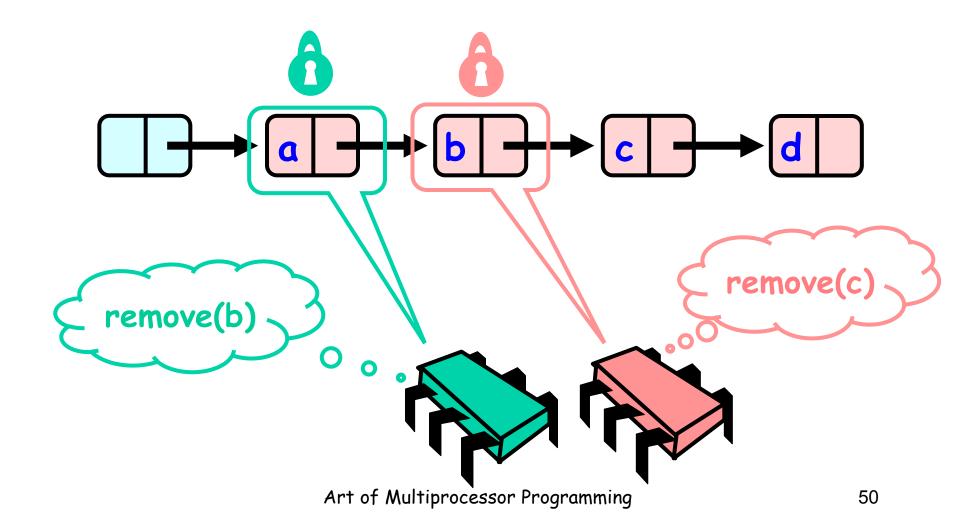

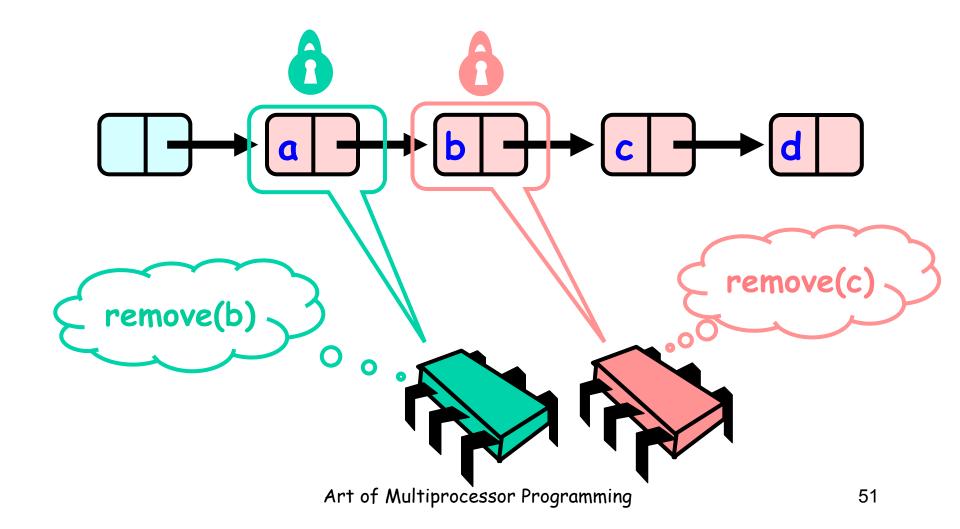

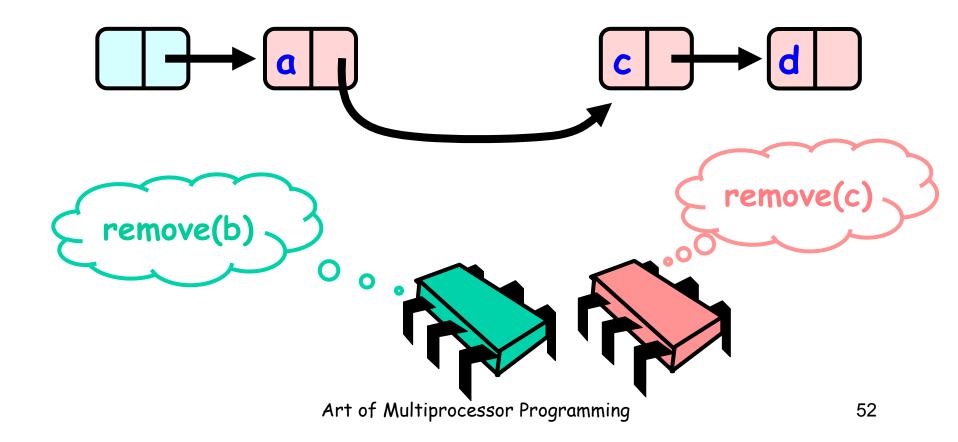

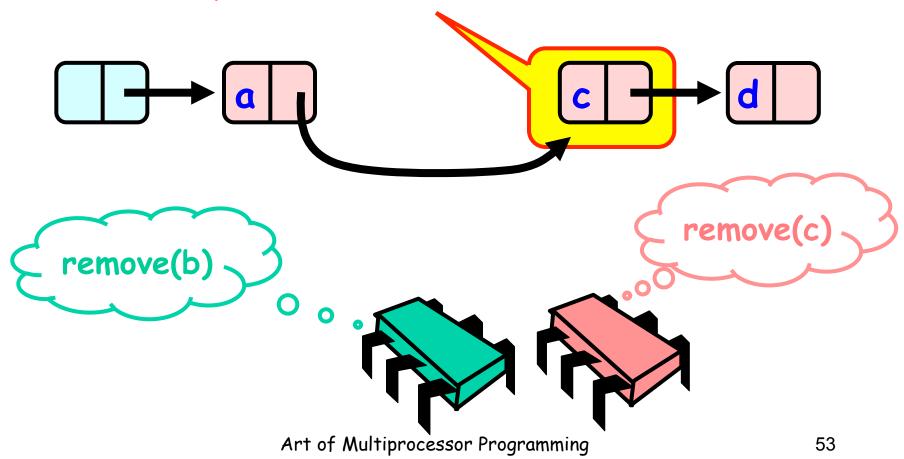

### Uh, Oh

### Uh, Oh

#### Bad news, C not removed

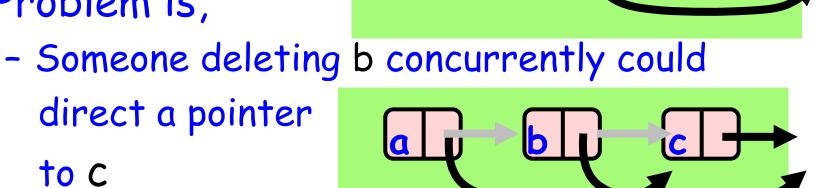

#### Problem

To delete node c

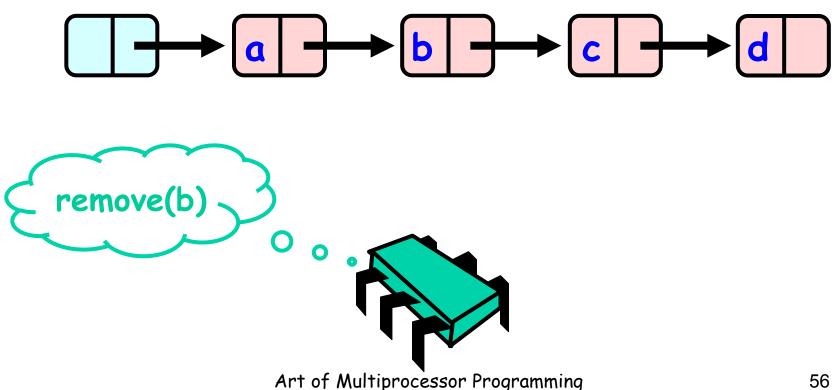

- Swing node b's next field to d

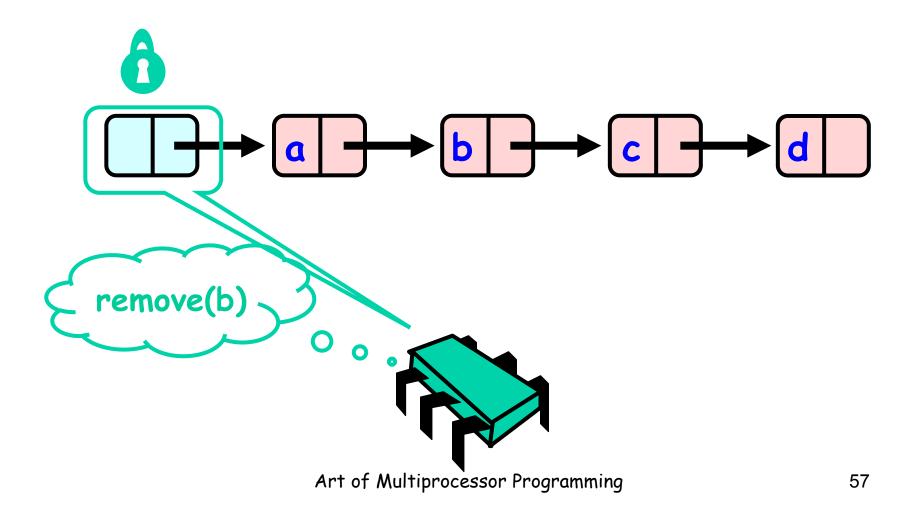

- Problem is,
  - direct a pointer to C

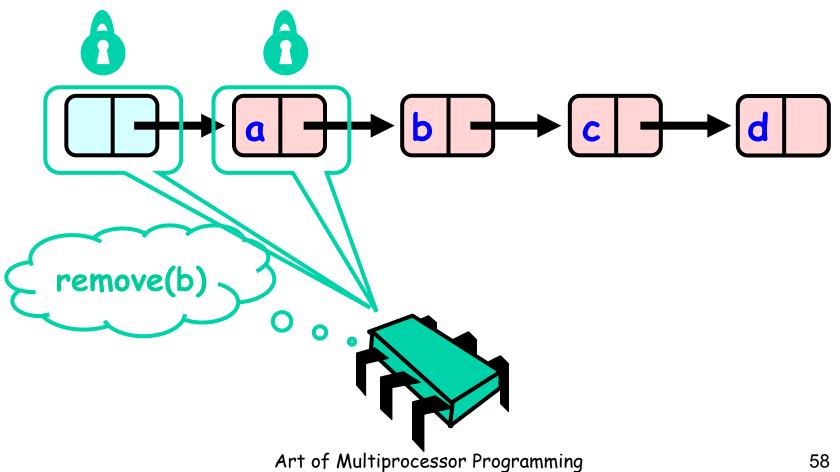

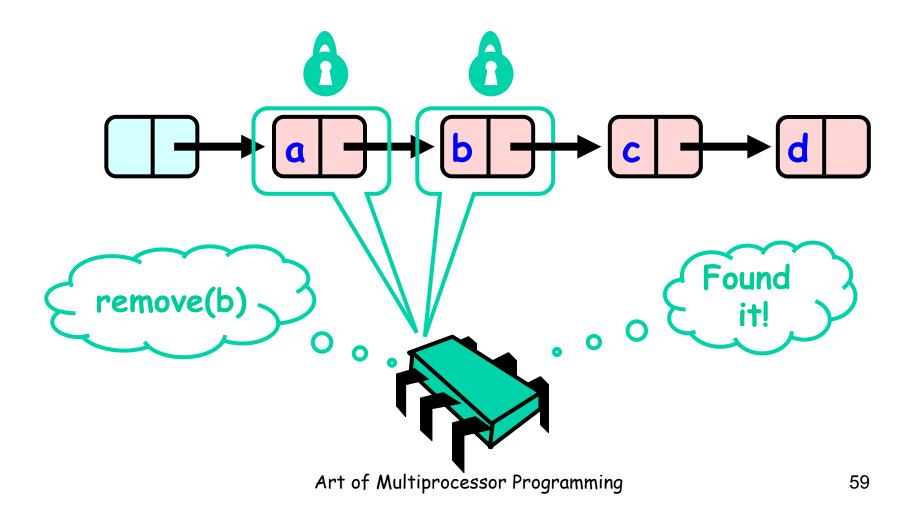

# Insight

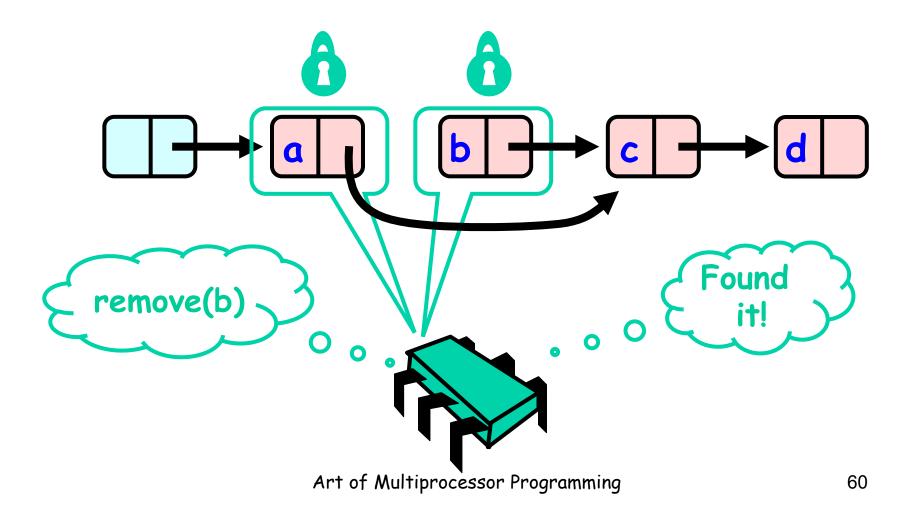

- If a node is locked
  - No one can delete node's successor
- If a thread locks
  - Node to be deleted
  - And its predecessor
  - Then it works

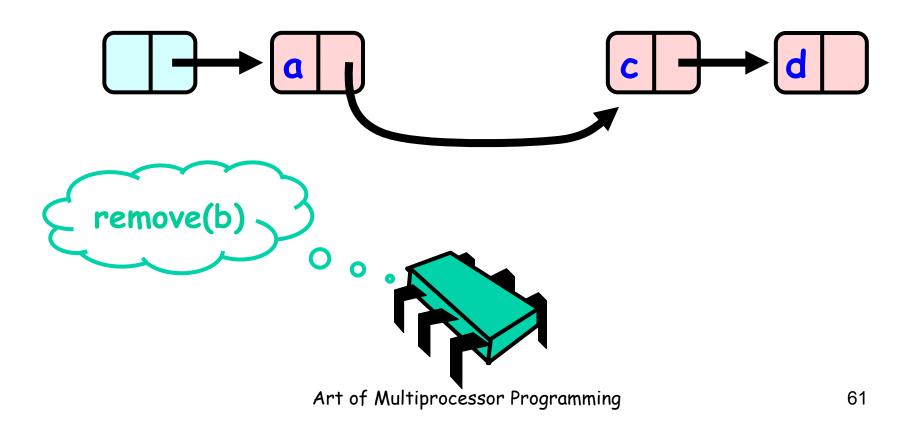

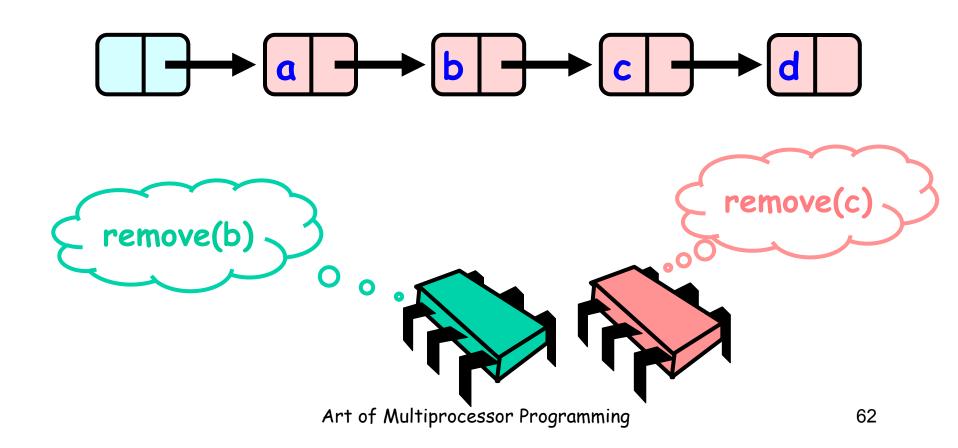

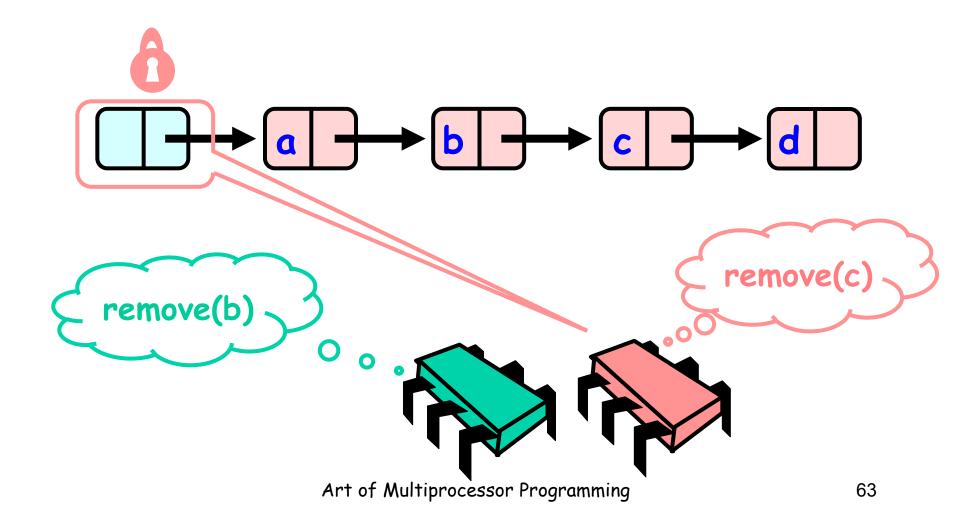

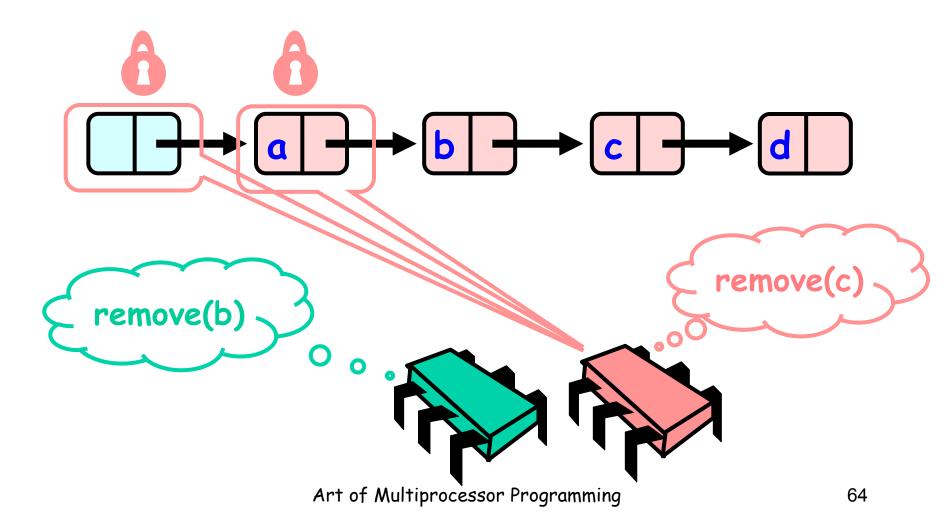

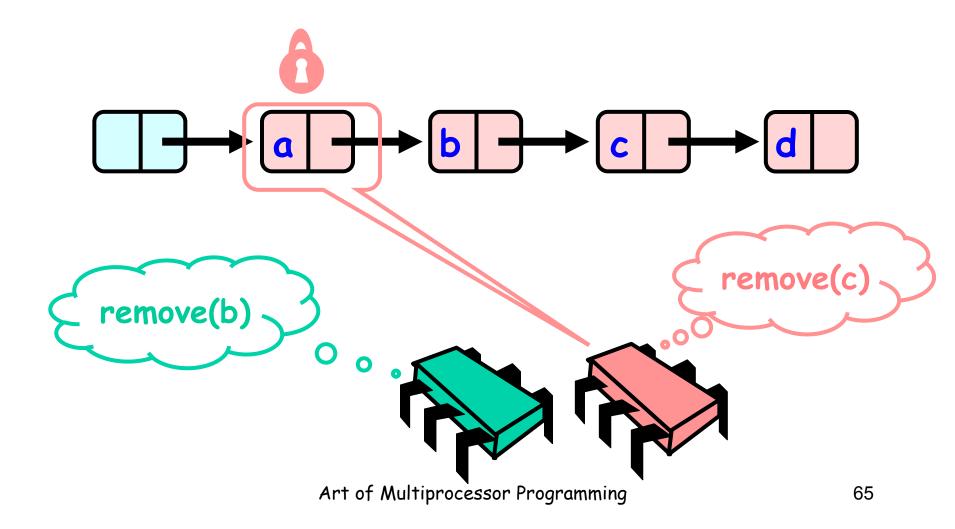

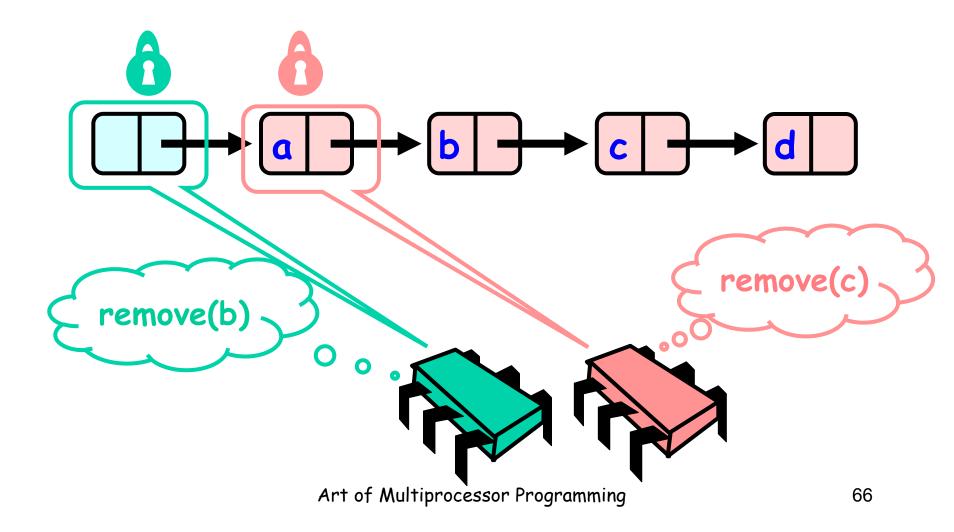

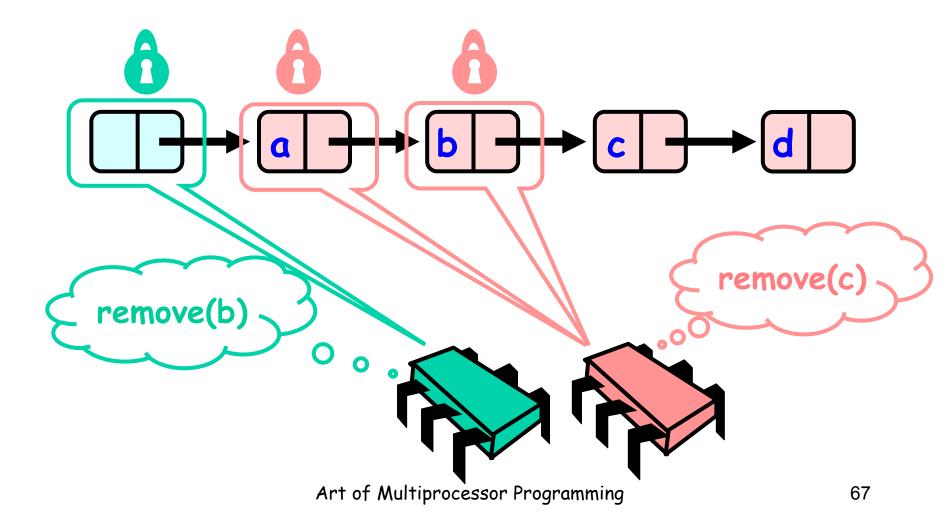

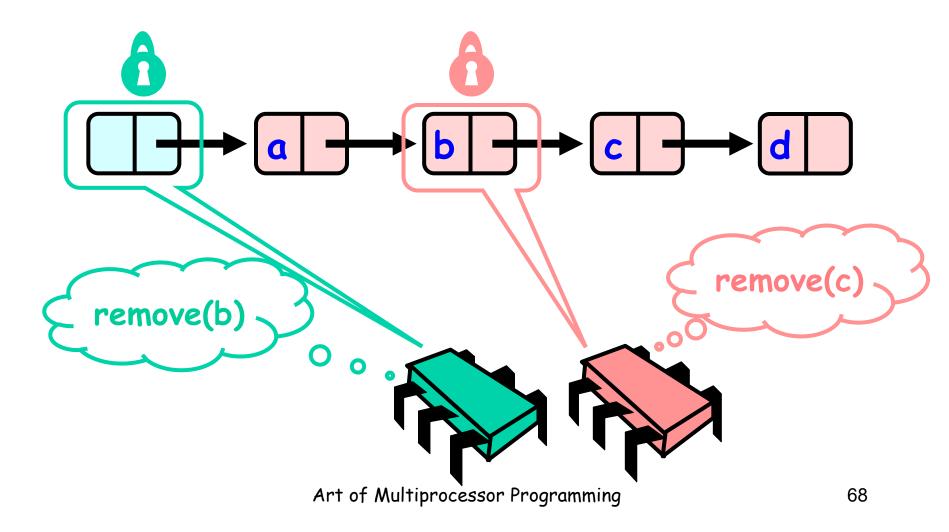

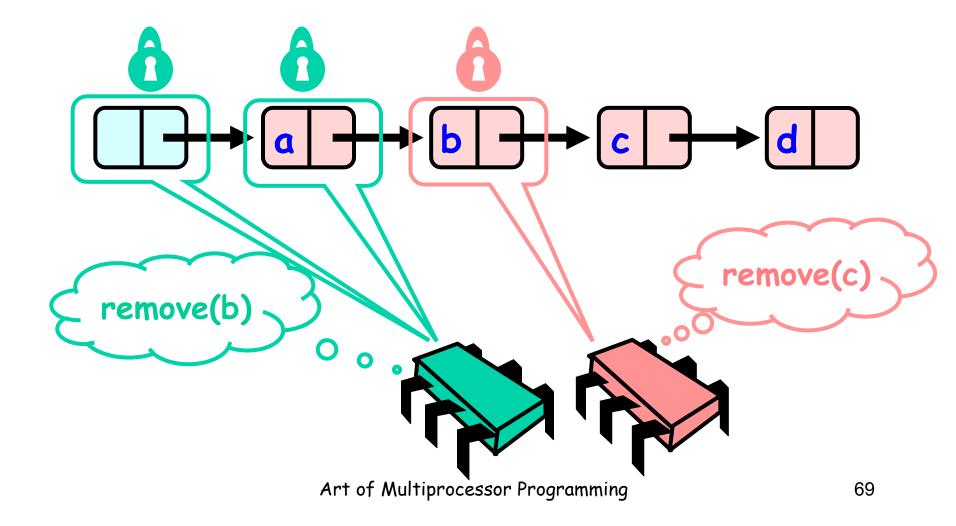

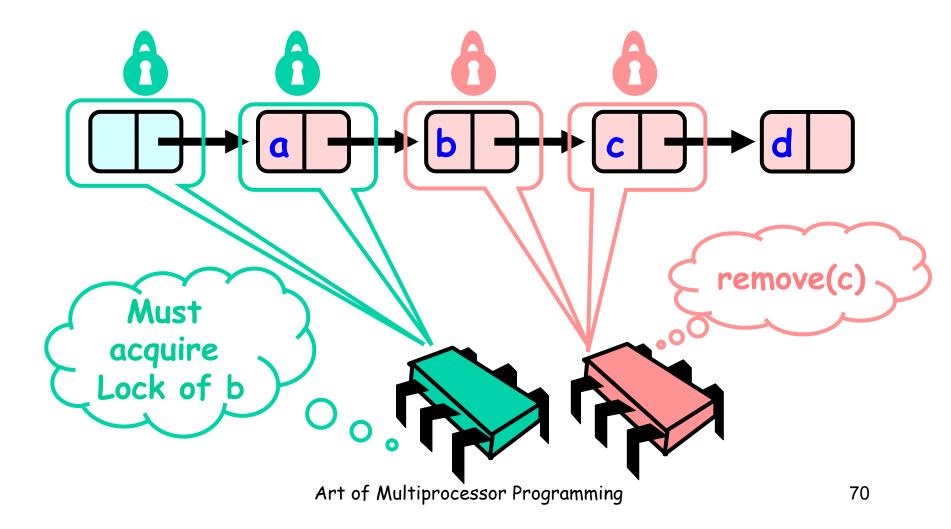

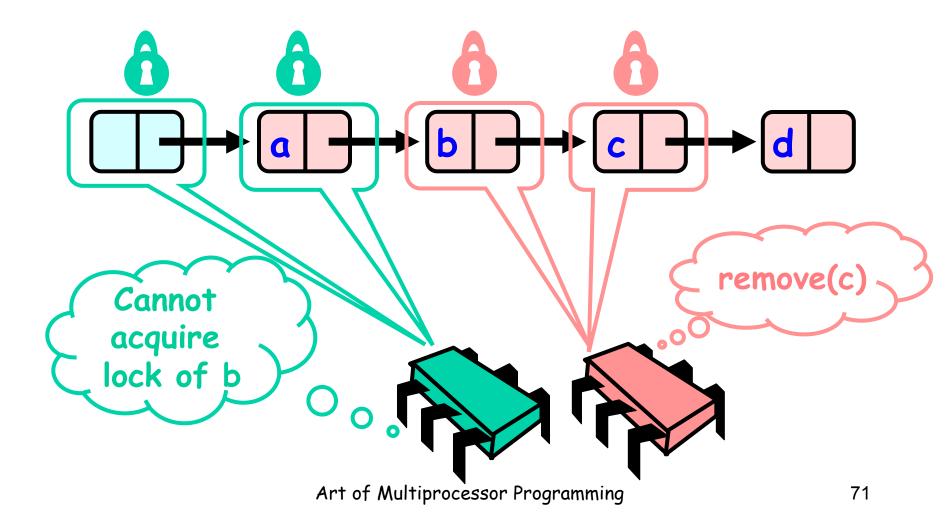

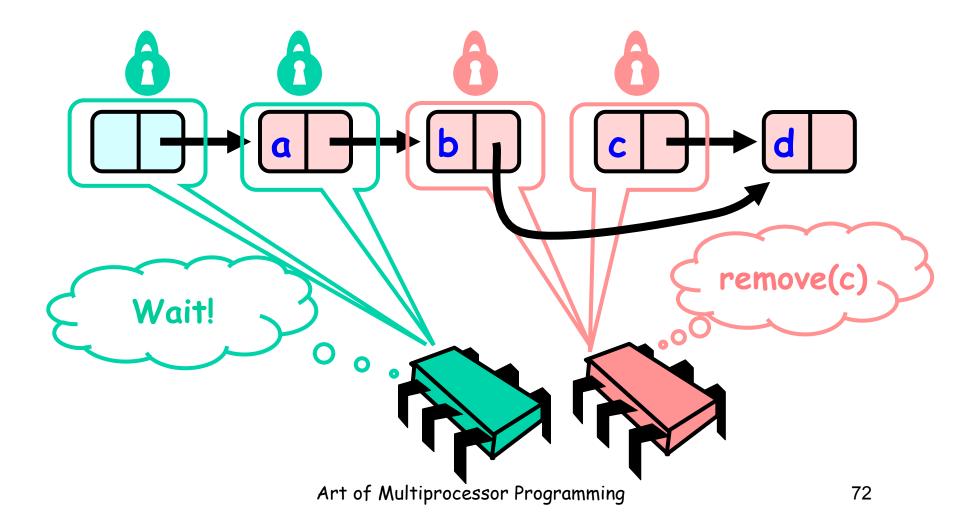

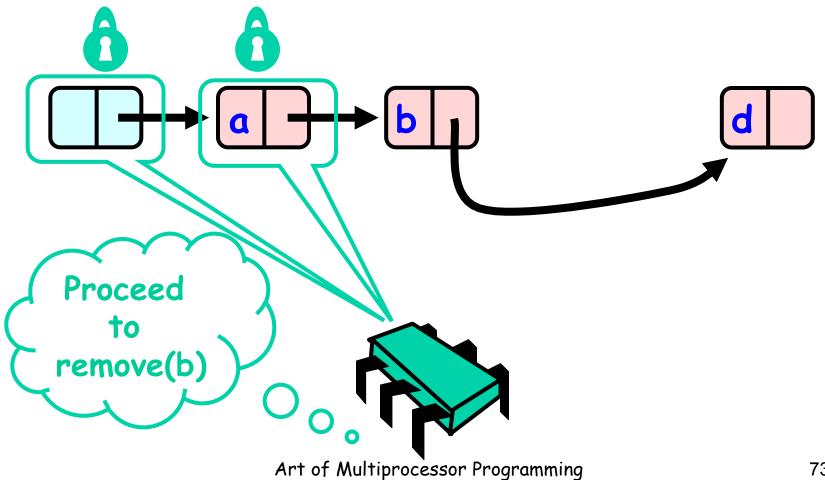

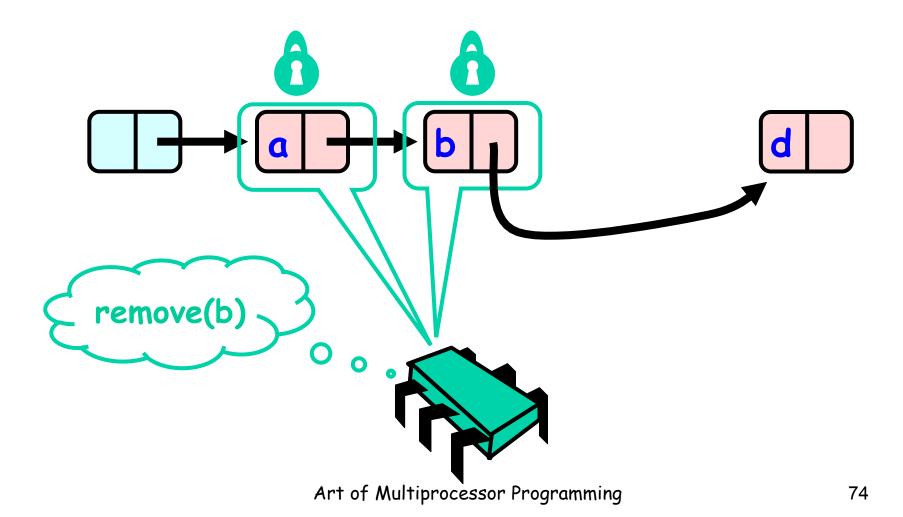

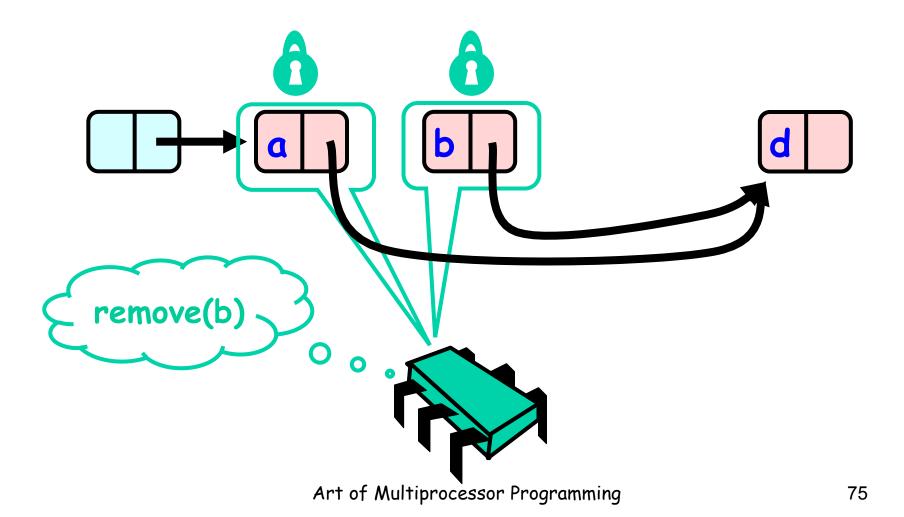

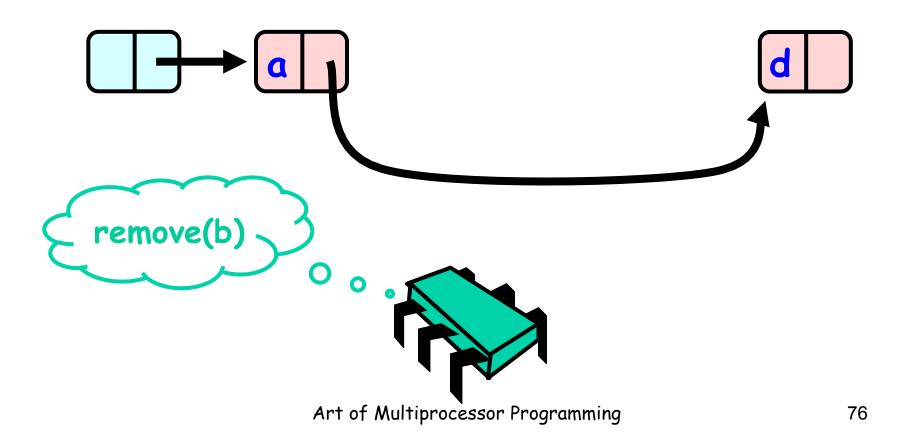

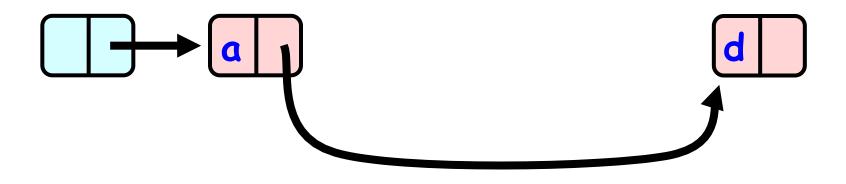

```
public boolean remove(Item item) {
  int key = item.hashCode();
  Node pred, curr;
  try {
    ...
  } finally {
    curr.unlock();
    pred.unlock();
  }}
```

```
public boolean remove(Item item) {
int key = item.hashCode();
Node pred, curr;
try {
} finally {
 curr.unlock();
 pred.unlock();
```

#### Key used to order node

```
public boolean remove(Item item) {
  int key = item.hashCode();
  Node pred, curr;
  try {
    ...
  } finally {
    currNode.unlock();
    predNode.unlock();
  }}
```

#### Predecessor and current nodes

```
public boolean remove(Item item) {
int key = item.hashCode();
Node pred, curr;
                            Make sure
                           locks released
  finally {
  curr.unlock();
  pred.unlock();
```

```
public boolean remove(Item item) {
  int key = item.hashCode();
  Node pred, curr;
  try {
    ...
  } finally {
    curr.unlock();
    pred.unlock();
    Everything else
  }}
```

```
try {
  pred = this.head;
  pred.lock();
  curr = pred.next;
  curr.lock();
...
} finally { ... }
```

```
lock pred == head
 pred = this.head;
 pred.lock();
  urr = pred.next;
 curr.lock();
} finally { ... }
```

```
try {
                       Lock current
 pred = this.head;
 curr = pred.next;
 curr.lock();
} finally { ... }
```

```
try {
 pred = this.head;
 pred.lock();
              Traversing list
 curr = pred mext;
  finally { ... }
```

```
while (curr.key <= key) {</pre>
  if (item == curr.item) {
   pred.next = curr.next;
   return true;
  pred.unlock();
  pred = curr;
  curr = curr.next;
  curr.lock();
 return false;
```

```
while (curr.key <= key) {</pre>
  if (item == curr item)
   pred.next = curr.next
   return true;
                    Search key range
  pred.unlock();
  pred = curr;
  curr = curr.next;
  curr.lock();
 return false;
```

```
while (curr.key <= key)</pre>
  if (item == curr.item) {
   pred.next = curr.next;
   return true;
  pred.unloAt start of each loop: curr
  pred = curr;
                   and pred locked
  curr = curr.next;
  curr.lock();
 return false;
              Art of Multiprocessor Programming
```

```
if (item == curr.item) {
  pred.next = curr.next;
  return true;
If item found, remove node
```

```
if (item == curr.item) {
  pred.next = curr.next;
  return true;
 pred.unloc
If node found, remove it
```

```
Unlock predecessor
while (curr.key <= key)
  if (item == curr.ite
   pred.next = cur
   return true
 pred.unlock();
  pred = curr;
  curr = curr.next;
  curr.lock();
 return false;
```

Only one node locked! while (cur\.key <= key) {</pre> if (item == curr.item) { pred.next = curr.next; return true; pred.unlock(); red = curr; curr = curr.next; curr.lock(); return false;

```
demote current
  pred.next/= curr.next;
  return tr
pred = curr;
     = curr.next;
curr.lock();
return false;
```

```
while (curr.key <= key) {
    Find and lock new current
    pred.next = curr.next;
    return true:
  pred.unlock()
  pred = currNode;
  curr = curr.next;
  curr.lock();
 return false;
```

```
Lock invariant restored
   pred.next = curr.next;
   return true;
  pred.unlock();
      d = currNode;
  <del>curr = curr.next;</del>
  curr.lock();
 return false;
```

```
while (curr.key <= key) {</pre>
  if (item == curr.item) {
   pred.next = curr.next;
   return true;
                Otherwise, not present
  pred.unlock();
  pred = curr;
  curr = curr.ne
  curr.lock()
 return false;
```

#### Why does this work?

- To remove node e
  - Must lock e
  - Must lock e's predecessor
- · Therefore, if you lock a node
  - It can't be removed
  - And neither can its successor

```
while (curr.key <= key)
 if (item == curr.item) {
   pred.next = curr.next;
   return true;
  pred.unlock();
  pred = curr;
  curr = curr.next
                    •pred reachable from head
  curr.lock();
                    ·curr is pred.next
                    ·So curr.item is in the set
 return false;
```

```
while (curr.key <= key) {</pre>
  if (item == curr.item) {
  pred.next = curr.next;
  pred.unlock();
  pred = curr;
  curr = curr.next;
  curr.lock();
                    Linearization point if
 return false;
                       item is present
```

```
while (curr.key <= key) {
  if (item == curr.item) {
   pred.next = curr.next;
   return true;
  pred.unlock();
  pred = curr;
  curr = curr.next;
  curr.lock();
                  Node locked, so no other
 return false;
                   thread can remove it ....
```

```
while (curr.key <= key) {</pre>
  if (item == curr.item) {
   pred.next = curr.next;
   return true;
  pred.unlock();
  pred = curr;
  curr = curr.next;
                        Item not present
  curr.lock();
 return false;
```

```
while (curr.key <= key) {</pre>
  if (item == curr.item) {
   pred.next = curr.next;
   return true;
  pred.unlock();
  pred = curr;
                      •pred reachable from head
  curr = curr.next
                      ·curr is pred.next
  curr.lock();
                      •pred.key < key</pre>
                      ·key < curr.key
 return false;
```

```
while (curr.key <= key) {</pre>
  if (item == curr.item) {
   pred.next = curr.next;
   return true;
                        Linearization point
  pred.unlock();
  pred = curr
  curr = curr.next;
  curr.lock();
 return false;
```

## Adding Nodes

- To add node e
  - Must lock predecessor
  - Must lock successor
- Neither can be deleted
  - (Is successor lock actually required?)

#### Same Abstraction Map

```
S(head) =
-{x | there exists a such that
· a reachable from head and
· a.item = x
-}
```

## Rep Invariant

- Easy to check that
  - tail always reachable from head
  - Nodes sorted, no duplicates

#### Drawbacks

- Better than coarse-grained lock
  - Threads can traverse in parallel
- Still not ideal
  - Long chain of acquire/release
  - Inefficient
